Goldbot One EA

Full Product Manual

Developed and Supported by Profalgo LTD

Version 3.0 (October 2026)

Dear Valued Client,

Welcome to the official complete user manual for **Goldbot One EA**, proudly developed by Profalgo LTD. This manual contains everything you need to successfully install, configure, and run Goldbot One on your MetaTrader 5 platform. We have designed this EA to be highly sophisticated yet remarkably easy to use.

What's New in Version 3.0

- Virtual Stop-Loss / Take-Profit: all trailing can now be handled internally by the EA and executed with market orders, instead of modifying orders at the broker.
- Two new news filters: Interest Rate (central bank rate decisions) and CPI (inflation). Both are off by default.
- The information panel now shows the correct profit and loss per strategy, including trades taken before this update.
- Fixed trade management on brokers whose trading session crosses midnight. On those brokers, trailing and other management could previously pause for most of the day.
- The information panel has been restyled to match our other EAs.

1. Introduction

Goldbot One EA is a powerful breakout trading robot engineered specifically for **XAUUSD (Gold)**.

It identifies high-probability breakouts of daily support and resistance levels and trades eight different optimized variations of the same core strategy. This multi-strategy approach provides excellent risk diversification and smoother equity growth over time.

Every trade is protected with predefined stop-loss and take-profit levels, plus advanced trailing stop-loss and trailing take-profit mechanisms (including a smart trailing take-profit that can exit early if price reverses). Goldbot One uses **no grid, no martingale, and no dangerous averaging** — only clean, professional risk management.

The EA automatically adapts internal parameters to the current gold price, so no frequent re-optimizations are needed when gold moves to new price levels. It is suitable for both conservative accounts and prop-firm challenges.

2. Key Features

- Multi-strategy breakout system with 8 independent variations for better diversification
- Trades breakouts of daily support and resistance levels on Gold
- One trade per strategy at any time for controlled risk
- Automatic adaptation to current Gold price levels
- Built-in NFP news filter with AutoGMT and MQL5 calendar support
- Prop-firm ready with randomization, daily drawdown protection, and unique trade adjustments
- Real-time information panel on the chart
- Robust risk management with multiple lot-sizing methods
- Regular free updates and dedicated support from Profalgo LTD

3. Strategy Overview

Goldbot One focuses exclusively on **XAUUSD** on the **Daily timeframe**. It detects breakouts of key daily support and resistance levels and uses eight different variations with unique entry and exit rules to capture moves in varying market conditions.

Each strategy runs independently and opens at most one trade at a time. You can enable or disable any of the eight strategies individually. The EA includes strict risk controls and dynamic trailing logic to protect profits and limit losses.

The system has been extensively tested with strong in-sample and out-of-sample performance across more than 20 years of data.

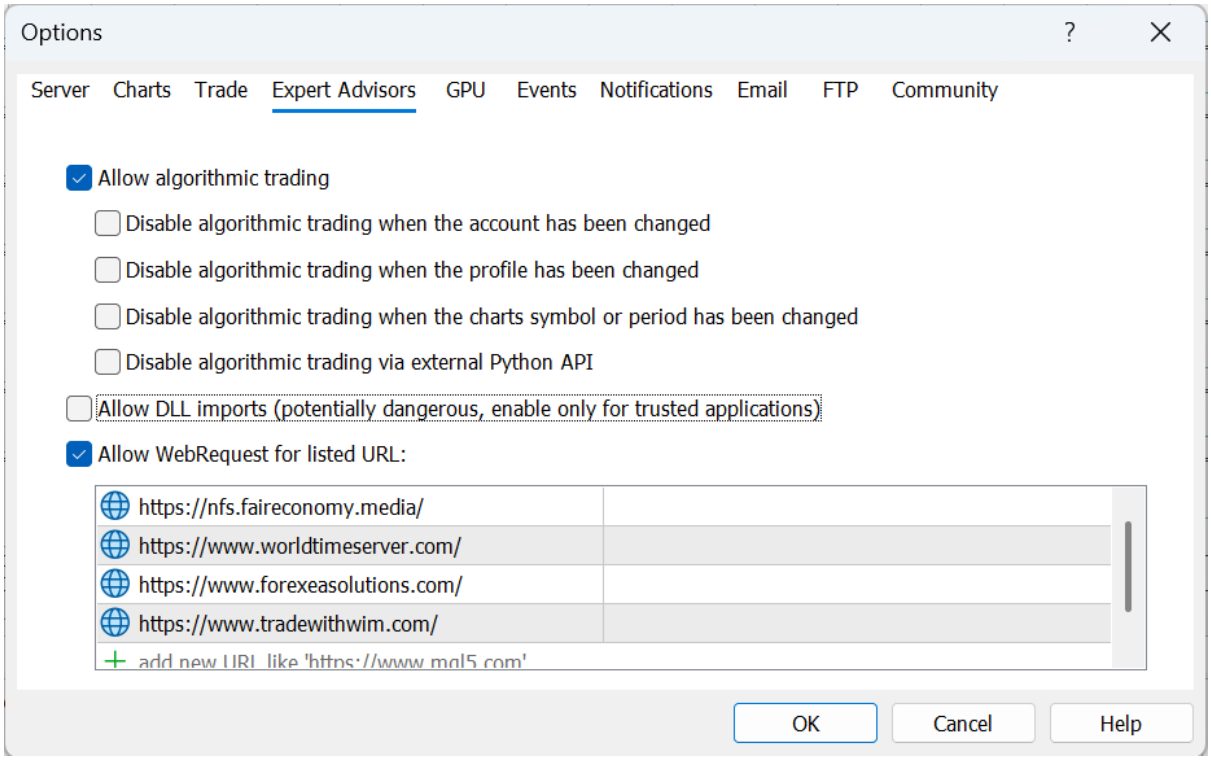

4. System Requirements

- MetaTrader 5 (latest build recommended)
- Trading symbol: **XAUUSD** (or GOLD – the EA automatically detects your broker's symbol)
- Recommended timeframe: **Daily** chart
- Minimum account balance: $600 (run max 4 strategies)
- Recommended account balance: 1500$ or more
- Recommended: Low-spread ECN broker for Gold
- VPS strongly recommended for 24/5 operation

Important – Allowed URLs (go to **Tools → Options → Expert Advisors** tab):

- https://forexeasolutions.org/ (if you purchased on forexeasolutions.com)
- https://forexeasolutions.services/ (if you purchased on forexeasolutions.com)
- https://www.tradewithwim.com/ (if you received from me directly)
- https://www.worldtimeserver.com/
- https://nfs.faireconomy.media/

These URLs support licensing, backup, AutoGMT, and the NFP news filter.

5. Installation

1. If you bought from our website: go to MT5 -> File -> Open Data Folder -> MQL5 -> Experts -> Advisors -> put the ex5 file there and restart the MT5
2. If you bought on MQL5.com: go to MT5 -> Tools -> options -> community -> fill in your MQL5 credentials. Then go to MT5 -> Market -> My Purchases -> Goldbot One -> install
3. Open an **XAUUSD Daily** chart.
4. Drag the **Goldbot One EA** onto the chart.
5. In the settings window, enable "**Allow live trading**" (AlgoTrading).
6. Click OK.
7. Make sure the **AutoTrading** button is enabled on the top toolbar.

The EA is now ready to trade once you configure the main risk parameters.

6. Quick Start Setup (Recommended by Profalgo LTD)

1. Attach the EA to an **XAUUSD Daily** chart.
2. Set **Lotsize calculation method** to **use Max Risk Per Strategy**.
3. Choose your risk level:
    - Low risk: **Max Risk Per Strategy = 3**
    - Medium risk: **Max Risk Per Strategy = 6–10** (default in screenshot)
    - Higher risk: **Max Risk Per Strategy = 15+**
4. Enable **AdjustLotsizeToVariableValues = true**.
5. Set **EnableNFP_Filter = true**, **UseMQL5Calendar = true**, and **AutoGMT = true**.
6. Leave **Fake Breakout Filter = ON**.
7. For **Prop-Firm Accounts**: Enable **Set Max Daily Drawdown**, set **Randomization** to 50 (or higher), and use the provided set files for quick setup.

7. Input Parameters – Full Explanation

License & General Settings

- **License Key (for non MQL5 version)** – Your licence key. This is only needed if you did not buy through MQL5.com -- for MQL5.com purchases the licence is handled automatically and this field stays empty. (default: empty)
- **License server** – The licence server the EA contacts to verify your copy. Do not change this. It must also be added to the allowed URL list in MT5 under Tools, Options, Expert Advisors, or the EA cannot start. (default: https://www.tradewithwim.com/)
- **Backup server** – A backup licence server, used automatically if the main one cannot be reached. Do not change this, and make sure it is in the allowed URL list alongside the main address. (default: https://forexeasolutions.services)
- **ShowInfoPanel** – Shows the live information panel on the chart: account and balance figures, the lot sizes in use, and the profit and loss of each individual strategy. Turn it off only if you run many charts on a weak VPS and want to save a little processing time. (default: true)
- **update infopanel during testing** – Draws and updates the information panel during Strategy Tester runs. It makes backtests noticeably slower, so it is off by default. Enable it only when you actually want to watch the panel while a test is running. (default: false)
- **Adjustment for Infopanel size** – Scales the whole information panel up or down. Increase it above 1.0 on high-resolution or 4K monitors where the panel looks too small, or decrease it below 1.0 if the panel takes up too much of the chart. (default: 1)
- **Force Font Size (0=disabled)** – Forces a specific font size for the information panel instead of letting the EA choose one from your screen resolution. Leave it at 0 unless the automatically chosen size does not suit your setup. (default: 0)
- **Backtest Speed** – Speeds up Strategy Tester runs by having the EA process fewer price updates per bar. This affects the Strategy Tester only and has no effect whatsoever on live trading. Use the faster settings for quick exploratory runs, then confirm your final results on normal, which is the most accurate. Options: normal, fast, ultra fast. (default: normal)

Trading Settings

- **Allow Buy Trades** – Allows the EA to open long positions. Switching this off stops new buy trades being opened but does not close or abandon any buy trade that is already running – those continue to be managed normally until they close. (default: true)
- **Allow Sell Trades** – Allows the EA to open short positions. As with buy trades, switching it off only stops new sell entries; anything already open continues to be managed until it closes. (default: true)
- **run strategy 1** – Switches individual strategies on and off. Lower-numbered strategies are generally the steadier ones, and running fewer strategies means fewer trades and a smaller drawdown. On a small account, start with a handful and add more as the balance grows. (default: true)
- **Max Allowed Spread** – The widest spread, in points, at which the EA will still place new orders. Above it, entries are held back until the spread comes in again, which protects you

during news spikes and thin market hours. It does not prevent existing trades from being managed or closed. Note that this value is also scaled by UseVariableValues, so it keeps pace with the Gold price. (default: 500.0)

- **Friday stop hour (brokertime; close all trades)** – The hour of the broker's clock on Friday at which the EA stops opening trades and closes everything still open, so nothing is carried over the weekend. Set it to 25 (or any value above 23) to disable the behaviour entirely and let trades run into the close. (default: 25)
- **setSL_TP_After_Entry** – A compatibility option for brokers that refuse pending orders which already carry a stop-loss and take-profit. When enabled, the EA sends the pending order without them and attaches both as soon as the order is filled. Leave it off unless your broker actually rejects orders, because it means there is a very brief moment after the fill before the stop is in place. (default: false)
- **Use Virtual Expiration** – Some brokers do not accept an expiry time on pending orders. With this enabled the EA does not ask the broker to expire them at all, and instead deletes them itself once they are old enough. The practical effect is the same, and it works on every broker, which is why it is on by default. (default: true)
- **Randomization (entries and exit) in pips** – Shifts entries, stops and targets by a small random amount, in pips, on every trade. It exists for prop-firm accounts: if you run the same EA on several accounts, identical trades across them can be flagged as copy trading. A value around 50 is a sensible starting point for prop firms. Leave it at 0 on a normal account, where it only adds noise. (default: 0)
- **Fake Breakout Filter** – Protection against false breakouts. After a trade opens, the EA checks whether the candle it entered on actually closed in the trade's favour; if that candle closed against the position, the trade is closed straight away rather than being left to run to its full stop-loss. The stronger settings apply the same check on more timeframes, which cuts losses sooner but also closes some trades that would have recovered. Options: OFF, ON. (default: ON)
- **Base Magicnumber** – The starting magic number the EA uses to tag its trades, so it can tell its own positions apart from everything else on the account. Each internal strategy gets its own number counting up from this one. Only change it if you run two copies of this same EA on one account, and then give each copy a base number far enough apart that the ranges cannot overlap. (default: 2000)
- **Comment for trades** – The comment attached to every trade the EA opens, which is what you see in your terminal and account history. Change it freely; it has no effect on trading. (default: GoldBot_One)
- **RemoveCommentSuffix** – By default the EA appends the strategy identifier to each trade comment, so you can see which strategy opened which trade. Enable this to strip that suffix and leave only your own comment text, which some prop firms and copy services prefer. (default: false)

NFP Filter

- **NFP_FILTER** section header.
- **EnableNFP_Filter** – Switches on the Non-Farm Payroll filter. NFP is the single most volatile scheduled event for Gold, with violent spikes in both directions and very wide spreads, so by

default the EA steps aside around it. The two settings below control whether it closes open trades, deletes pending orders, or both. (default: true)

- **UseMQL5Calendar** – Takes the exact release time from the economic calendar built into MT5 rather than from the EA's internal table of dates. This is the more accurate option and we recommend leaving it on. It needs the MT5 calendar to be populated – on a fresh VPS, open Toolbox, Calendar once and let it sync. In the Strategy Tester the calendar is not available, so the EA automatically falls back to its internal dates. (default: true)
- **AutoGMT** – Works out your broker's GMT offset automatically, which is what the news filter needs in order to convert release times into your broker's clock. Leave it on for live trading. The two manual offsets below are used only when this is off, or when backtesting. (default: true)
- **GMT_OFFSET_Winter (AutoGMT=false or backtesting)** – Your broker's GMT offset during winter time, used when AutoGMT is off or when backtesting. Getting this wrong shifts the news windows by whole hours, so check it against your broker's stated server time rather than guessing. (default: 2)
- **GMT_OFFSET_Summer (AutoGMT=false or backtesting)** – Your broker's GMT offset during summer (daylight saving) time, used when AutoGMT is off or when backtesting. Most brokers move their clock by one hour in summer, so this is usually the winter value plus one. (default: 3)
- **NFP_CloseOpenTrades** – Closes any open trades before the NFP release. Switch it off if you would rather let running trades take their chances through the news and only stop new orders being placed. (default: true)
- **NFP_ClosePendingOrders** – Deletes resting pending orders before the NFP release, so a spike cannot trigger an entry in the middle of the chaos. The EA places fresh orders again once the window has passed. (default: true)
- **NFP_MinutesBefore** – How many minutes before the release the filter starts. Increase it if your broker's spread begins widening well ahead of the announcement. (default: 180)
- **NFP_MinutesAfter** – How many minutes after the release the EA waits before trading again. Increase it if you want to sit out the whipsaw that often follows the first reaction. (default: 50)

Interest Rate Filter

The Interest Rate and CPI filters work the same way as the NFP filter and can be used alongside it. Both are switched off by default, so nothing changes unless you enable them.

- **EnableIR_Filter** – Switches on the interest-rate filter, which covers scheduled central bank rate decisions. These move Gold sharply and are worth avoiding for the same reasons as NFP. It is off by default, so nothing changes unless you turn it on, and it can be used alongside the NFP and CPI filters. (default: false)
- **IR_CloseOpenTrades** – Closes open trades before the rate decision. Switch it off to leave running trades alone and only block new entries. (default: true)
- **IR_ClosePendingOrders** – Deletes resting pending orders before the rate decision, so the spike cannot trigger an entry. Fresh orders are placed again afterwards. (default: true)

- **IR_MinutesBefore** – How many minutes before the rate decision the filter starts. (default: 100)
- **IR_MinutesAfter** – How many minutes after the rate decision the EA waits before trading again. Rate decisions are often followed by a press conference that moves the market a second time, so a longer window than usual can be sensible here. (default: 60)

CPI Filter

- **EnableCPI_Filter** – Switches on the CPI (inflation) filter. CPI releases are one of the main drivers of Gold and routinely cause large, fast moves. It is off by default, and can be used alongside the NFP and interest-rate filters. (default: false)
- **CPI_CloseOpenTrades** – Closes open trades before the CPI release. Switch it off to leave running trades alone and only block new entries. (default: true)
- **CPI_ClosePendingOrders** – Deletes resting pending orders before the CPI release, so the spike cannot trigger an entry. Fresh orders are placed again afterwards. (default: true)
- **CPI_MinutesBefore** – How many minutes before the CPI release the filter starts. (default: 100)
- **CPI_MinutesAfter** – How many minutes after the CPI release the EA waits before trading again. (default: 60)

Virtual Stop-Loss / Take-Profit

By default the EA places a real Stop-Loss and Take-Profit on the server and moves them as the trade develops. With Virtual SL/TP enabled, the initial Stop-Loss and Take-Profit are still placed on the server exactly as before, but every later adjustment is kept internally by the EA and executed with a market order instead. Your trade is therefore never unprotected. This is useful on brokers with wide stop levels, or where frequent order modifications are discouraged.

- **Enable Virtual SL/TP (trailing by market close)** – Changes how the EA moves your stop and target once a trade is running. Normally every adjustment is sent to the broker as an order modification. With this enabled the EA keeps the moving levels in its own memory instead and closes the trade with a market order when one is reached. The original stop-loss and take-profit are still placed on the server exactly as before, so the trade is never unprotected. This helps on brokers with wide minimum stop distances, or where constant order modifications are discouraged. The trade-off is that the EA must be running and connected for the virtual levels to be acted on. (default: false)
- **Seconds before the real SL is pulled up to the virtual SL** – Only applies when Virtual SL/TP is enabled. It sets how long the EA waits before also pulling the real stop-loss at the broker up to the virtual level, which gives you server-side protection even if your VPS goes down. Set it to 0 to keep the exit completely virtual, in which case the real stop-loss is never moved from where it started and the trade is always closed by market order unless that original stop is hit. (default: 99)

Propfirm unique trades settings

- **AdjustEntry** – Shifts every entry price by this many pips. Together with the other adjustments below, it exists so that the same EA running on several prop-firm accounts does not place identical trades, which can be flagged as copy trading. Leave it at 0 on a normal account. (default: 0)

- **AdjustSL** – Shifts every stop-loss by this many pips. A positive value widens the stop and therefore increases the risk per trade, so change it in small steps and remember that your lot sizing is based on the original distance. (default: 0)
- **AdjustTP** – Shifts every take-profit by this many pips, making targets slightly nearer or further away than standard. (default: 0)
- **AdjustTrailSL** – Shifts the trailing stop distance by this many pips, so the trail sits a little tighter or looser than standard. (default: 0)
- **AdjustBE** – Shifts the break-even level by this many pips, changing how much profit is locked in when the trade reaches break-even. (default: 0)

LotSize Settings

- **Set Balance To Use manually** – Makes the EA size its trades from a fixed balance figure instead of your real account balance. Useful when you want to trade only part of an account, or to keep lot sizes steady while you add or withdraw funds. Leave it at 0 to use the real balance. (default: 0)
- **StartLots** – The fixed lot size used when the lot size calculation method is set to the manual option. It is ignored by every other method. Note this is the lot size per strategy, not for the account as a whole, so the total exposure depends on how many strategies are running. (default: 0.01)
- **Lotsize calculation method** – Chooses how the EA works out its lot sizes. This is the most important setting in this section, because it decides which of the values below actually does anything – the others are ignored. Options: use StartLots, use Max Risk Per Strategy, use lotsizeStep. (default: use StartLots)
- **Max Risk Per Strategy** – The maximum risk, as a percentage, allotted to each individual strategy, based on its historical drawdown. Because every running strategy gets this allowance, total account exposure is roughly this figure multiplied by the number of active strategies. Raise it gradually once you are comfortable with how the EA behaves. (default: 6)
- **Set Max Daily Drawdown (Prop Firms)** – A hard daily loss limit, as a percentage. If the account loses this much in a single day the EA closes everything and stops trading until the next day. It exists for prop-firm rules that fail an account on daily loss. Set it a little tighter than the firm's actual limit so that spread and slippage cannot push you past the line. 0 disables it. (default: 0)
- **LotsizeStep** – Used by the lot-size-step method: the EA adds one more minimum lot for every this much account balance. A value of 1000, for example, means 0.01 lots per 1000 of balance. It is the simplest and most predictable of the methods, and ignores drawdown entirely. (default: 1000)
- **OnlyUp** – Stops lot sizes from shrinking after losses. The EA remembers the highest balance the account has reached and keeps sizing from that figure, so a drawdown does not also cut your position sizes and slow the recovery. The trade-off is that risk stays at the higher level while the account is down, so it is more aggressive than letting lots fall away. (default: false)
- **CheckMargin** – Checks that enough free margin is available before sending an order, and skips the trade if not. Leave it on – it prevents rejected orders and margin warnings on smaller accounts. (default: true)

- **Use Equity Instead of Balance** – Sizes trades from account equity rather than balance, which means open floating profit or loss is taken into account. This makes the EA reduce size while trades are under water and increase it while they are in profit, which is a more conservative approach but also a more variable one. (default: false)
- **AdjustLotsizeToVariableValues** – Works together with UseVariableValues. When the scaling widens the stop-loss distance, the same lot size would risk more money than intended, so this reduces the lot size to compensate (and increases it again when distances shrink). Leave it on whenever UseVariableValues is on, otherwise your real risk per trade drifts as the Gold price changes. (default: true)
- **Reset Highest Balance for OnlyUp** – Clears the highest-balance figure that OnlyUp remembers, so lot sizing starts again from your current balance. Use it after a withdrawal, or if you want the EA to trade smaller following a drawdown. Enable it, let the EA run for one tick, then set it back to false. (default: false)

8. Recommended Risk Management

The most important parameter is **Max Risk Per Strategy**.

We recommend starting with **use Max Risk Per Strategy** as the calculation method.

- Low risk: 3
- Medium risk: 6–10
- Higher risk: 15+

Keep **AdjustLotsizeToVariableValues = true**, **AutoGMT = true**, **EnableNFP_Filter = true**, and **Fake Breakout Filter = ON**.

For prop firms, enable **Set Max Daily Drawdown** and use **Randomization** around 50.

9. Backtesting Recommendations

- Use **XAUUSD Daily** chart.
- Modeling quality: “1 Minute OHLC” (or real ticks if available).
- Test at least one full year, preferably longer (2016–2024 recommended).
- Set **Lotsize calculation method** to “use Max Risk Per Strategy” for realistic results.
- Always verify performance on a demo account before going live.

10. Support

As a Goldbot One owner, you have full access to our support:

- Fast replies via our email (info@forexeasolutions.com) and MQL5 private messages
- Private Discord Community: https://discord.gg/MQ32NhUamK
- Regular free updates
- Dedicated guidance and custom .set files

We are here to help you succeed with our EA.

11. Risk Disclaimer

Trading the financial markets carries a high level of risk and is not suitable for everyone. Past performance does not guarantee future results. Goldbot One EA is a trading tool, not a money-printing machine. Only use risk capital you can afford to lose. We recommend thorough testing in a demo environment before going live.

Thank you for choosing **Profalgo LTD**. We wish you consistent and profitable trading with **Goldbot One EA**.

Best regards,

Profalgo LTD Team

Wim Schrynemakers
